The Open-PSA Initiative

Model Exchange Format for Probabilistic Safety Analyses

Towards a New Generation of Models and Tools

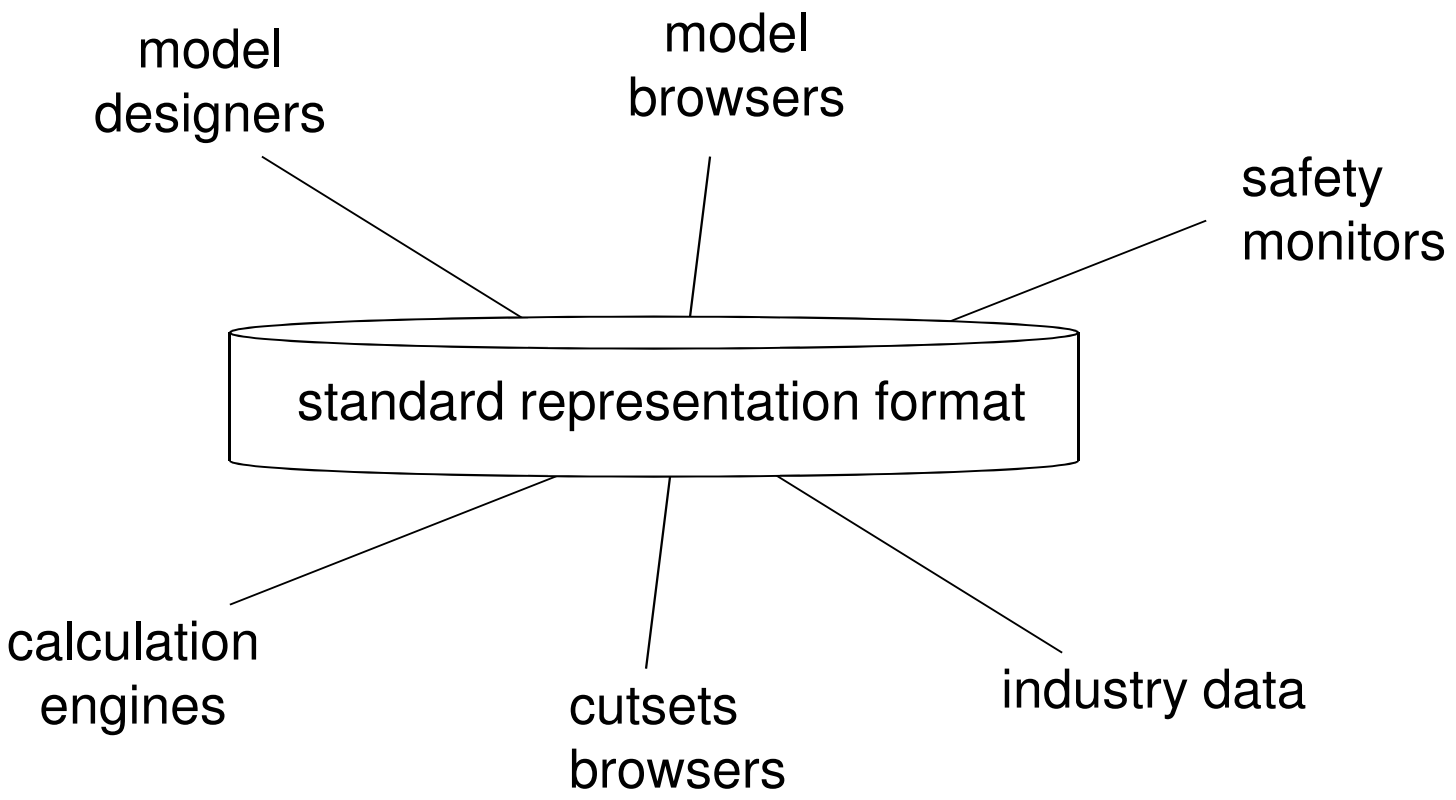
Why Do We Need a Standard?

- Reduce tool dependency
- Have a better confidence in approximations (quality insurance)
- Cross check calculations
- Develop new calculation engines
- Design new model browsers and safety monitors
- Review and document (existing) models
- Clarify (unify?) modeling methodologies
- Call external tools (Level 2 PSA)
- Extend fault trees/events trees formalism
- …

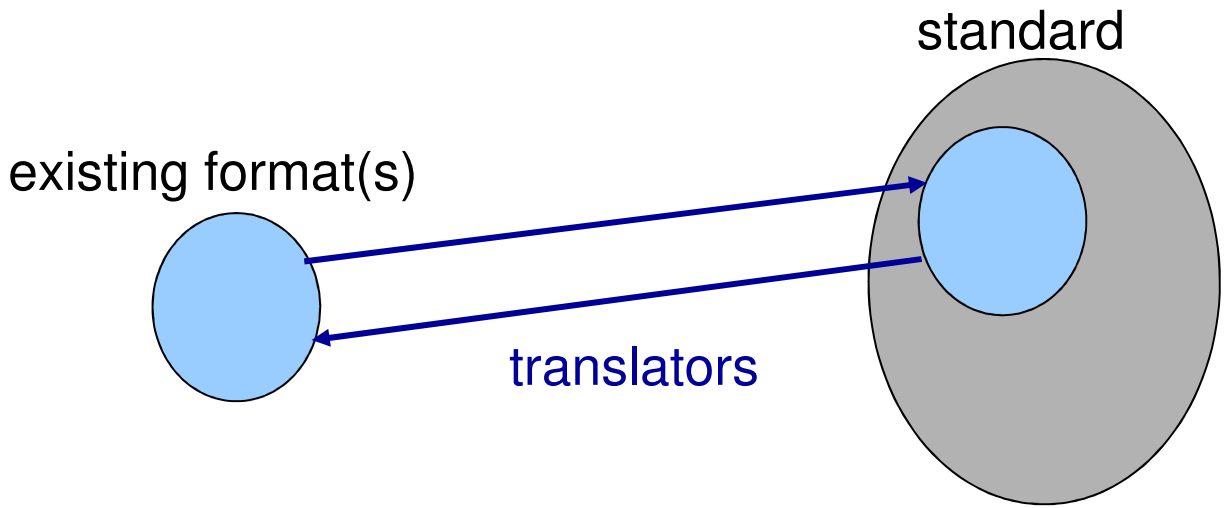
The Open-PSA Initiative

The Open-PSA Architecture



Requirements

- It should be possible to cast any existing model



- The role of each element should be clearly identified and have an unambiguous semantics
- The standard should be easy to embed in existing tools and easy to extend

… XML format

The Open-PSA Initiative

Anatomy of the Standard

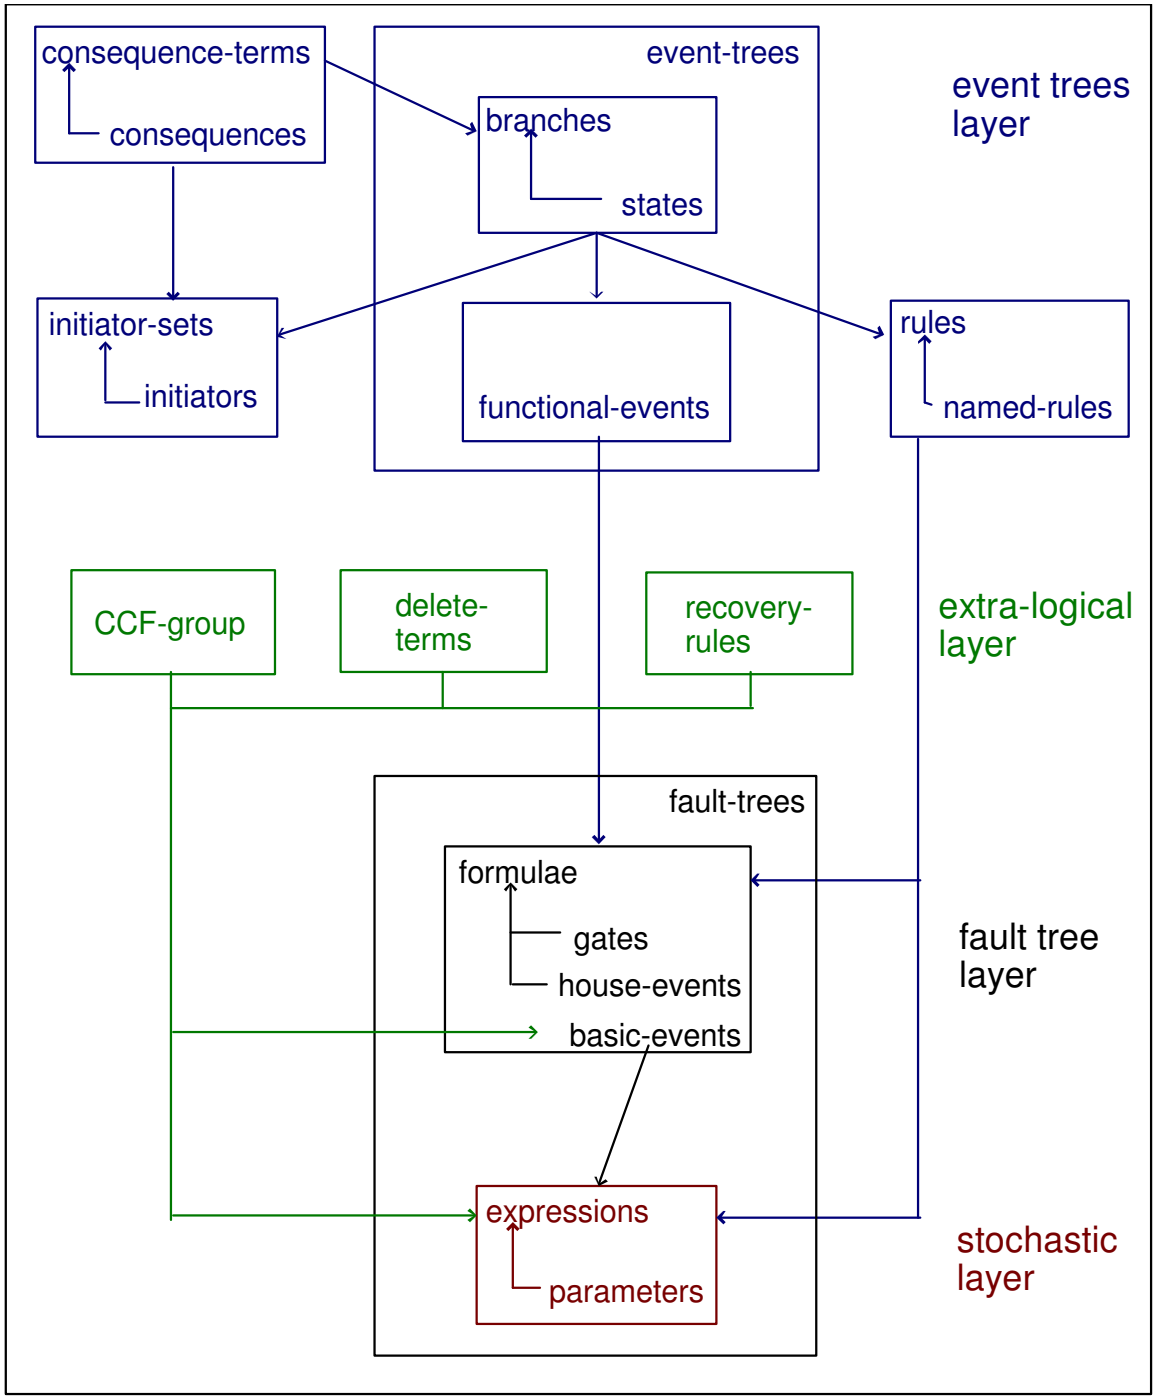
Methodology

- We considered models built with the main tools available on the market
  - Cafta, Saphire, RiskSpectrum, Riskman, Fault Tree free...
  - US, Japanese and European PSA
- We made of taxonomy of all syntactic categories we found in these models
  - Gates, basic events, house events, sequences...
- We gave to each category a formal operational semantics
- We designed a XML representation of categories

Five Layers Architecture

- Report Layer
  - Results of calculation...
- Event Tree Layer
  - Event trees, initiators, sequences, consequences
- Extra-Logical Layer
  - CCF-groups, delete terms, exchange events...
- Fault Tree Layer
  - Fault Trees, gates, basic events, house events
- Stochastic Layer
  - Probability distributions, parameters

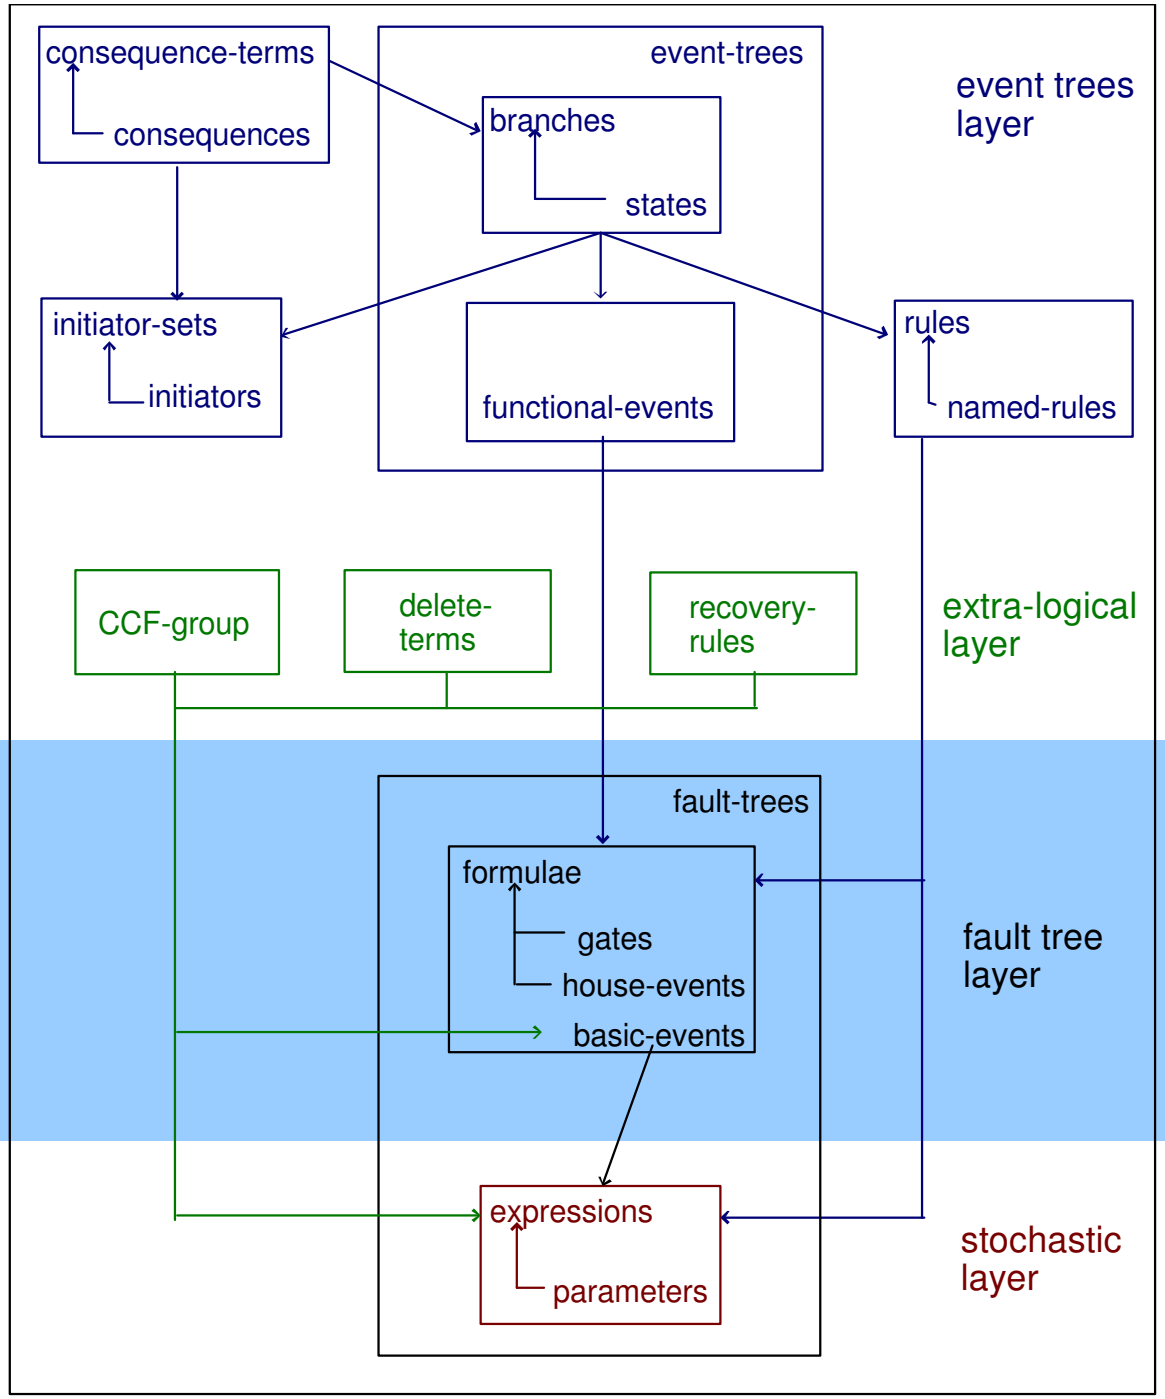
The Open-PSA Initiative



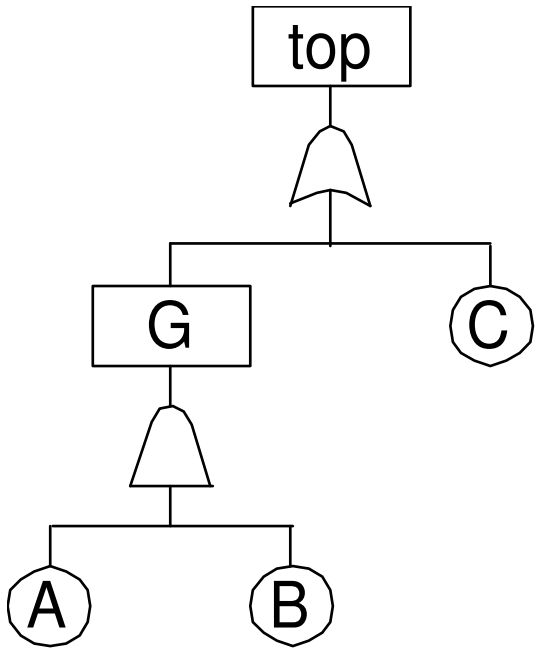
The Open-PSA Initiative

Fault Tree Layer

The Open-PSA Initiative



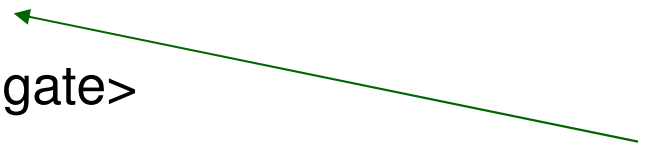
Declarations of Fault Trees



```
<define-fault-tree name="FT1" >
   <define-gate name="top" >
      <or>
         <gate name="G" />
         <basic-event name="C" />
      </or>
   </define-gate>
   <define-gate name="G" >
      <and>
         <basic-event name="A" />
         <basic-event name="B" />
      </and>
   </define-gate>
</define-fault-tree>
```

Declarations of Gates

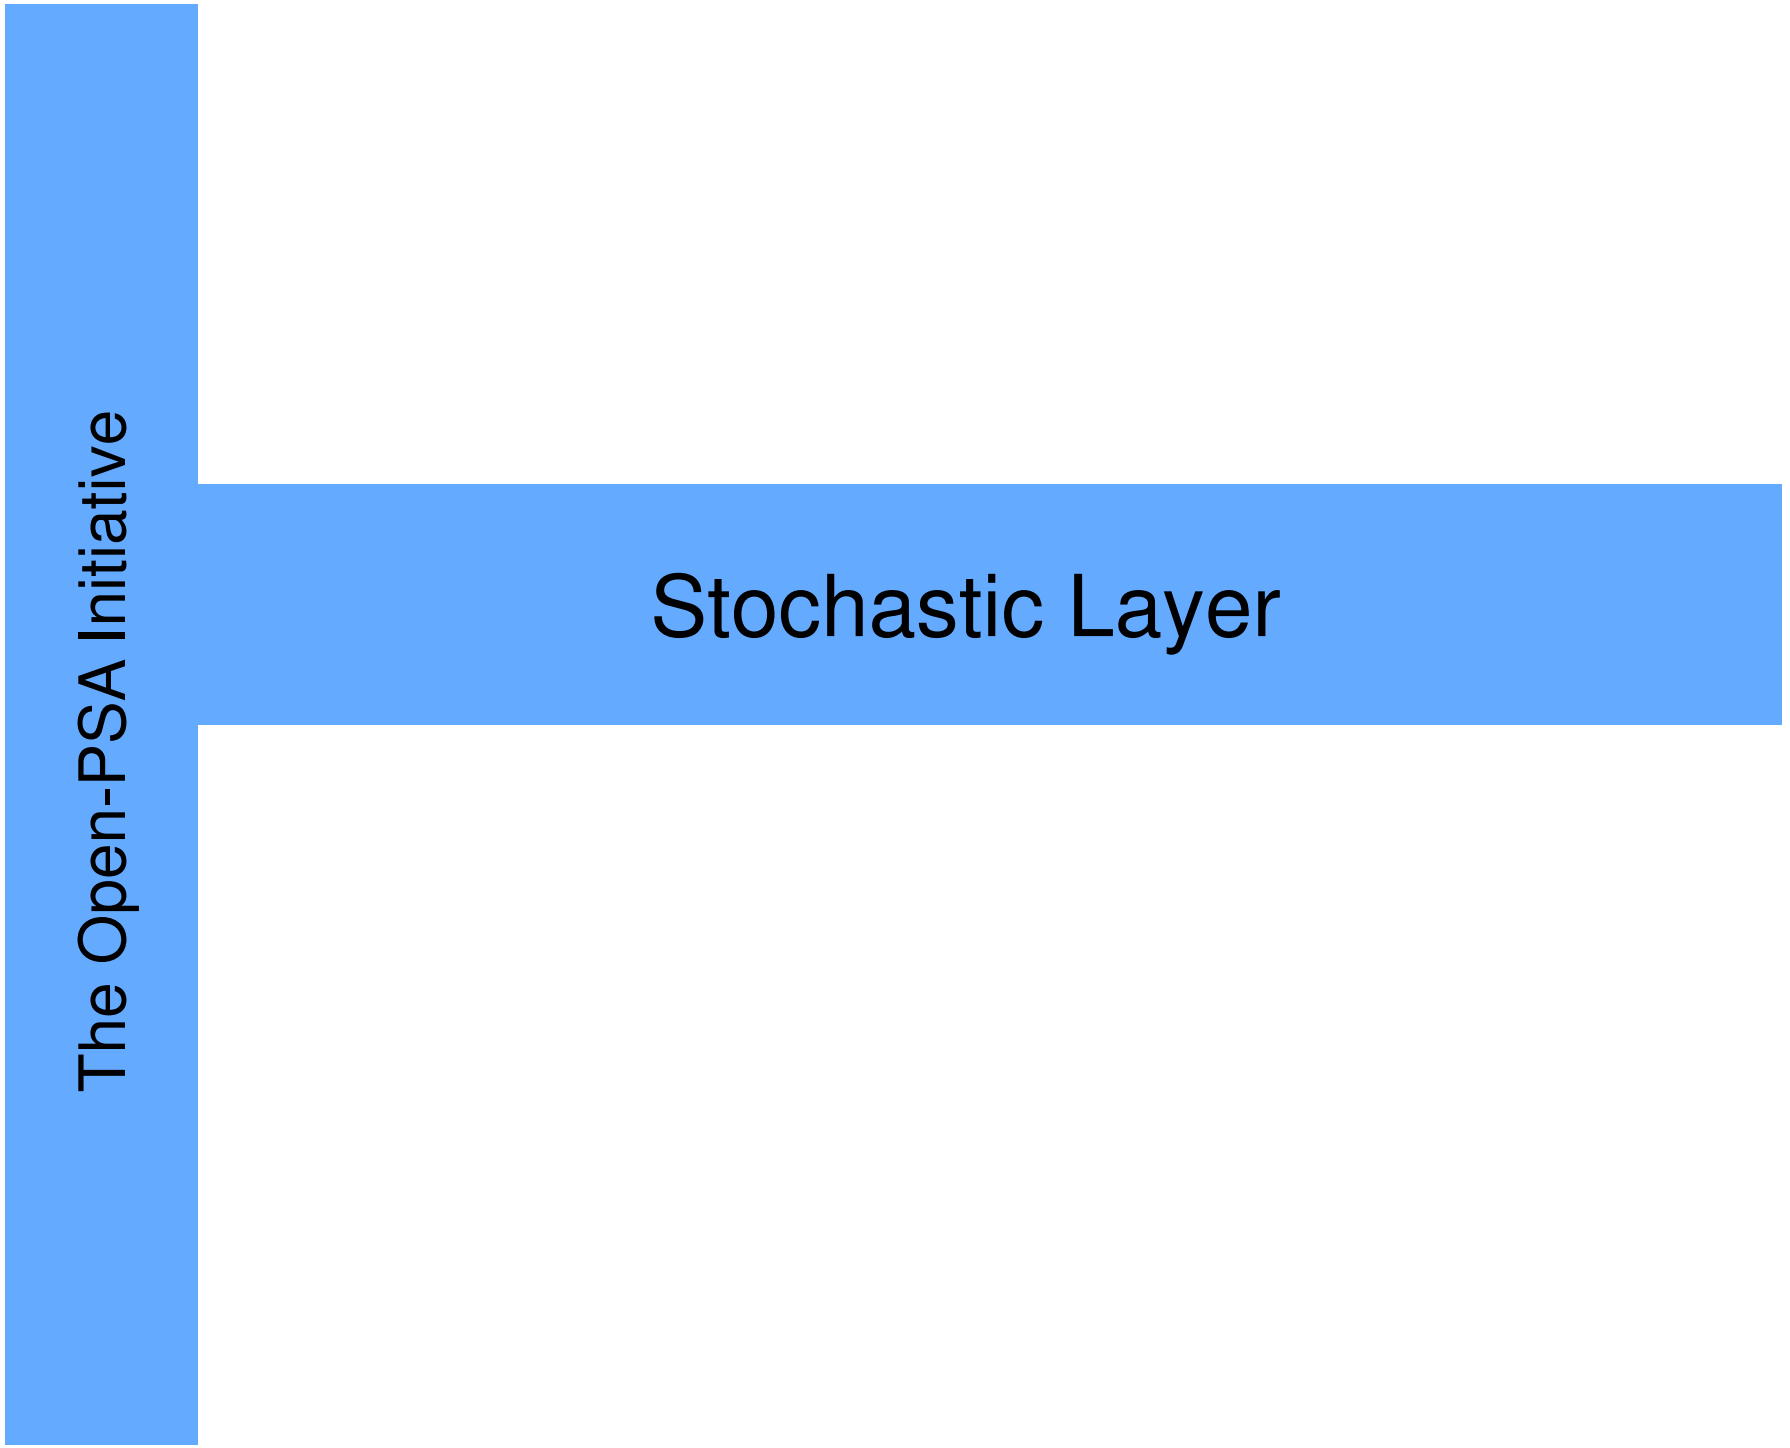
```
<define-gate name="valve-failed-closed">
    <or>
        <basic-event name="valve-hardware-failure" />
        <gate name="valve-human-failure" />
        <basic-event name="valve-test-failure" />
    </or>
</define-gate>
```



the standard provides a complete set of logical connectives

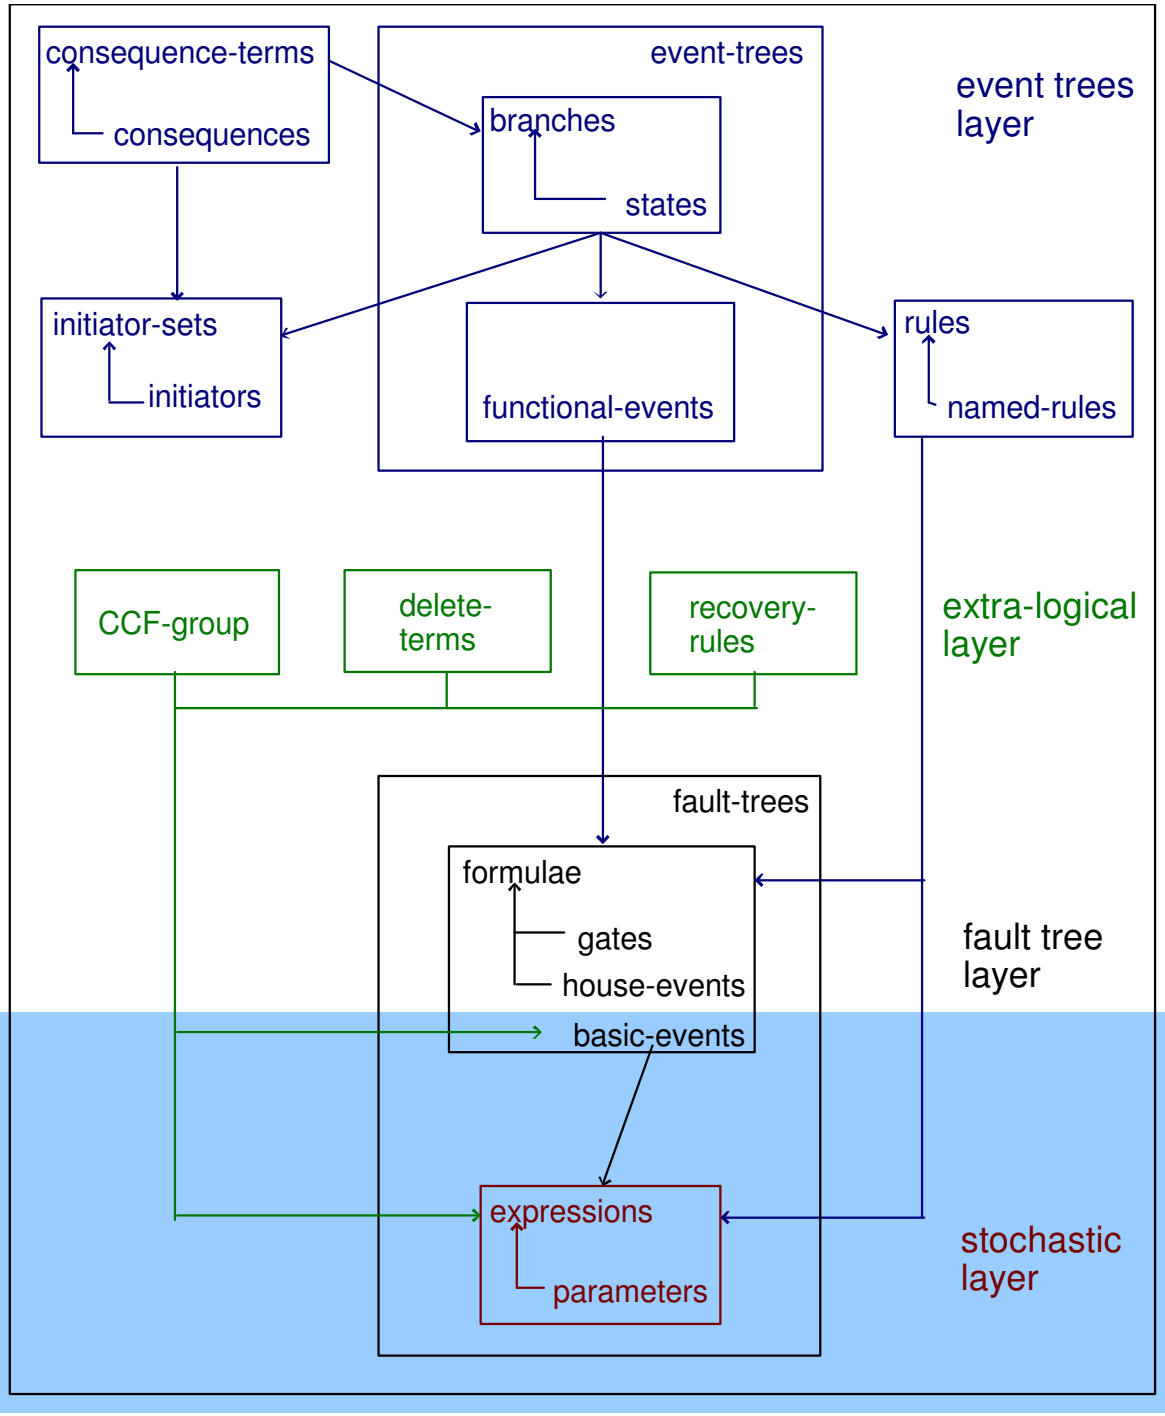
Declarations of Basic Events

```
<define-basic-event name="valve-hardware-failure" >
    <exponential>
        <parameter name="failure-rate-valves" />
        <mission-time />
    </exponential>
</define-basic-event>
```



The Open-PSA Initiative
Stochastic Layer

The Open-PSA Initiative



Stochastic Layer (Content)

1. Stochastic expression and parameters
   role and definition
2. Operations
   Arithmetic operations, logical operations, conditional operations
3. Built-ins
   usual time-dependent distributions
4. Random Deviates
   uniform, normal, lognormal deviates, histograms

Role of Stochastic Expressions

1. Associate (possibly time-dependent) probabilities with basic events. E.g.

```
<define-basic-event name="BE">
  <exponential>                          negative exponential distribution
    <parameter name="lambda" />          failure rate
    <mission-time />                     mission time
  </exponential>
</define-basic-event>
```

2. Define distributions for these probabilities (and more generally for parameters). E.g.

```
<define-basic-event name="BE2">
  <uniform-deviate>                      uniform random deviate
    <float value="1.0e-4" />             lower bound
    <float value="2.0e-4" />             upper bound
  </uniform-deviate>
</define-basic-event>
```

Built-ins

Set of predefined function to describe time-dependent distributions.

E.g.

- <exponential>
  <parameter name="failure-rate-pump" />
  <mission-time />
  </exponential>
- <Weibull>
  <parameter name="shape1" />
  <parameter name="scale1" />
  <sub>
  <mission-time />
  <parameter name="locality1" />
  </sub>
  </Weibull>
- ...

Random-Deviates

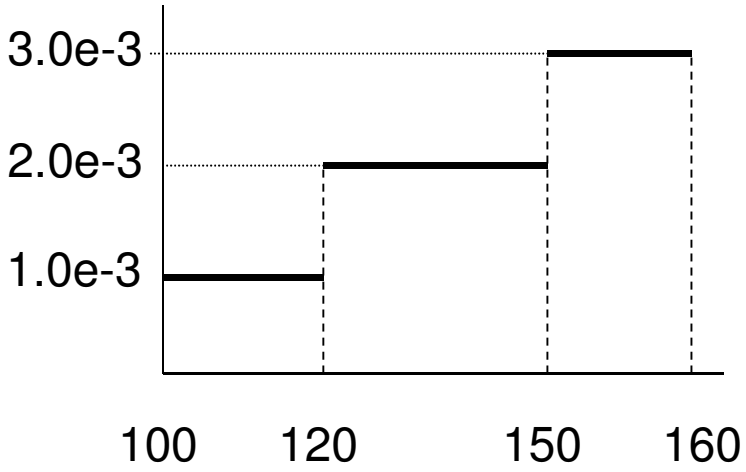
To perform sensitivity analyses. E.g.

- <uniform>
  <float value="1.0e-3" /> *lower-bound*
  <float value="2.0e-3" /> *upper-bound*
  </uniform>

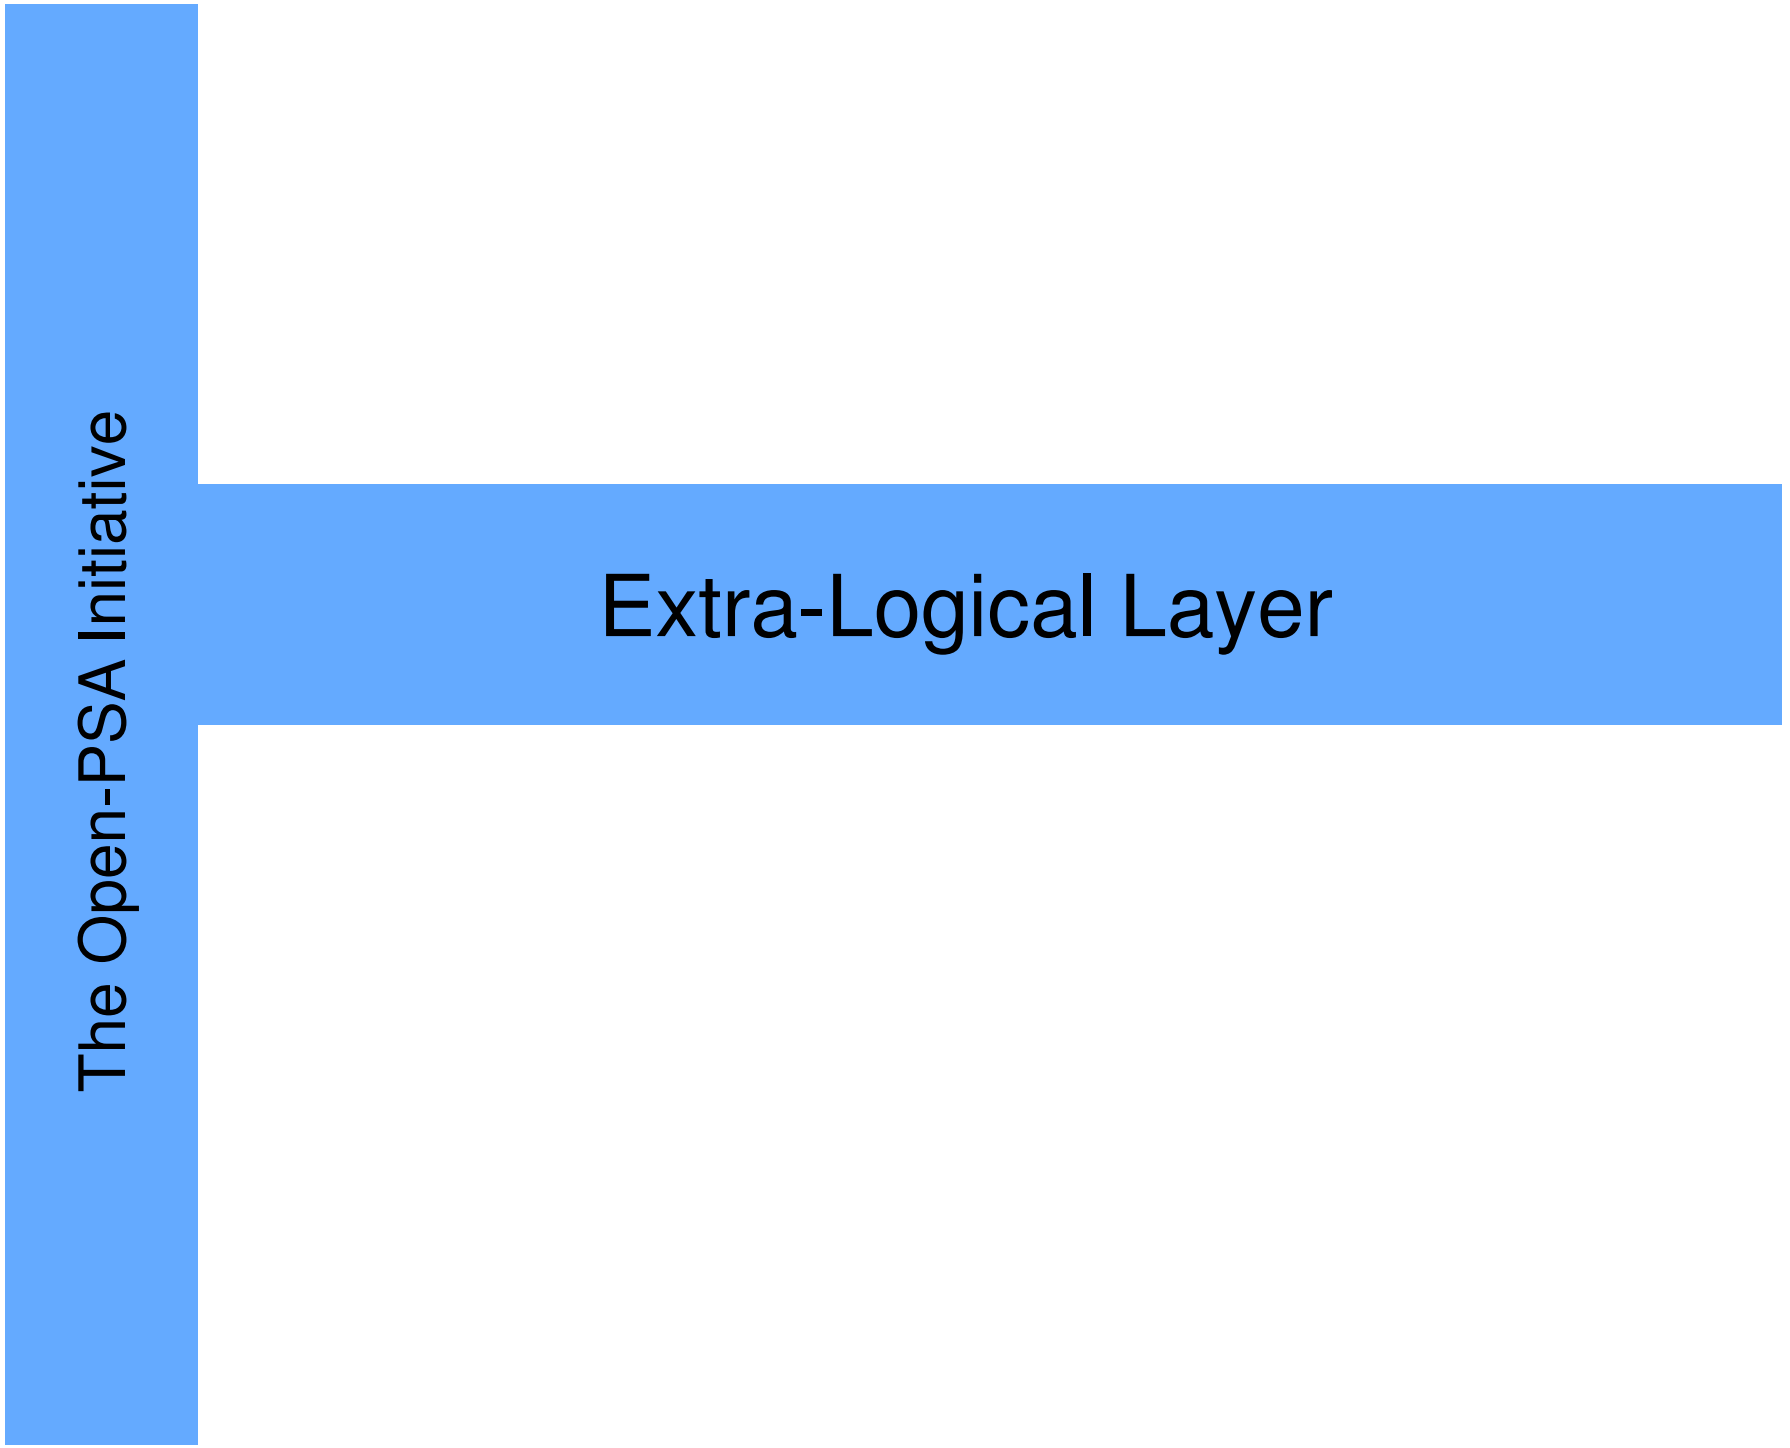
- <lognormal>
  <float value="1.23e-4" /> *mean*
  <int value="3" /> *error-factor*
  <float value="0.90" /> *confidence*
  </lognormal>

- ...

Histograms

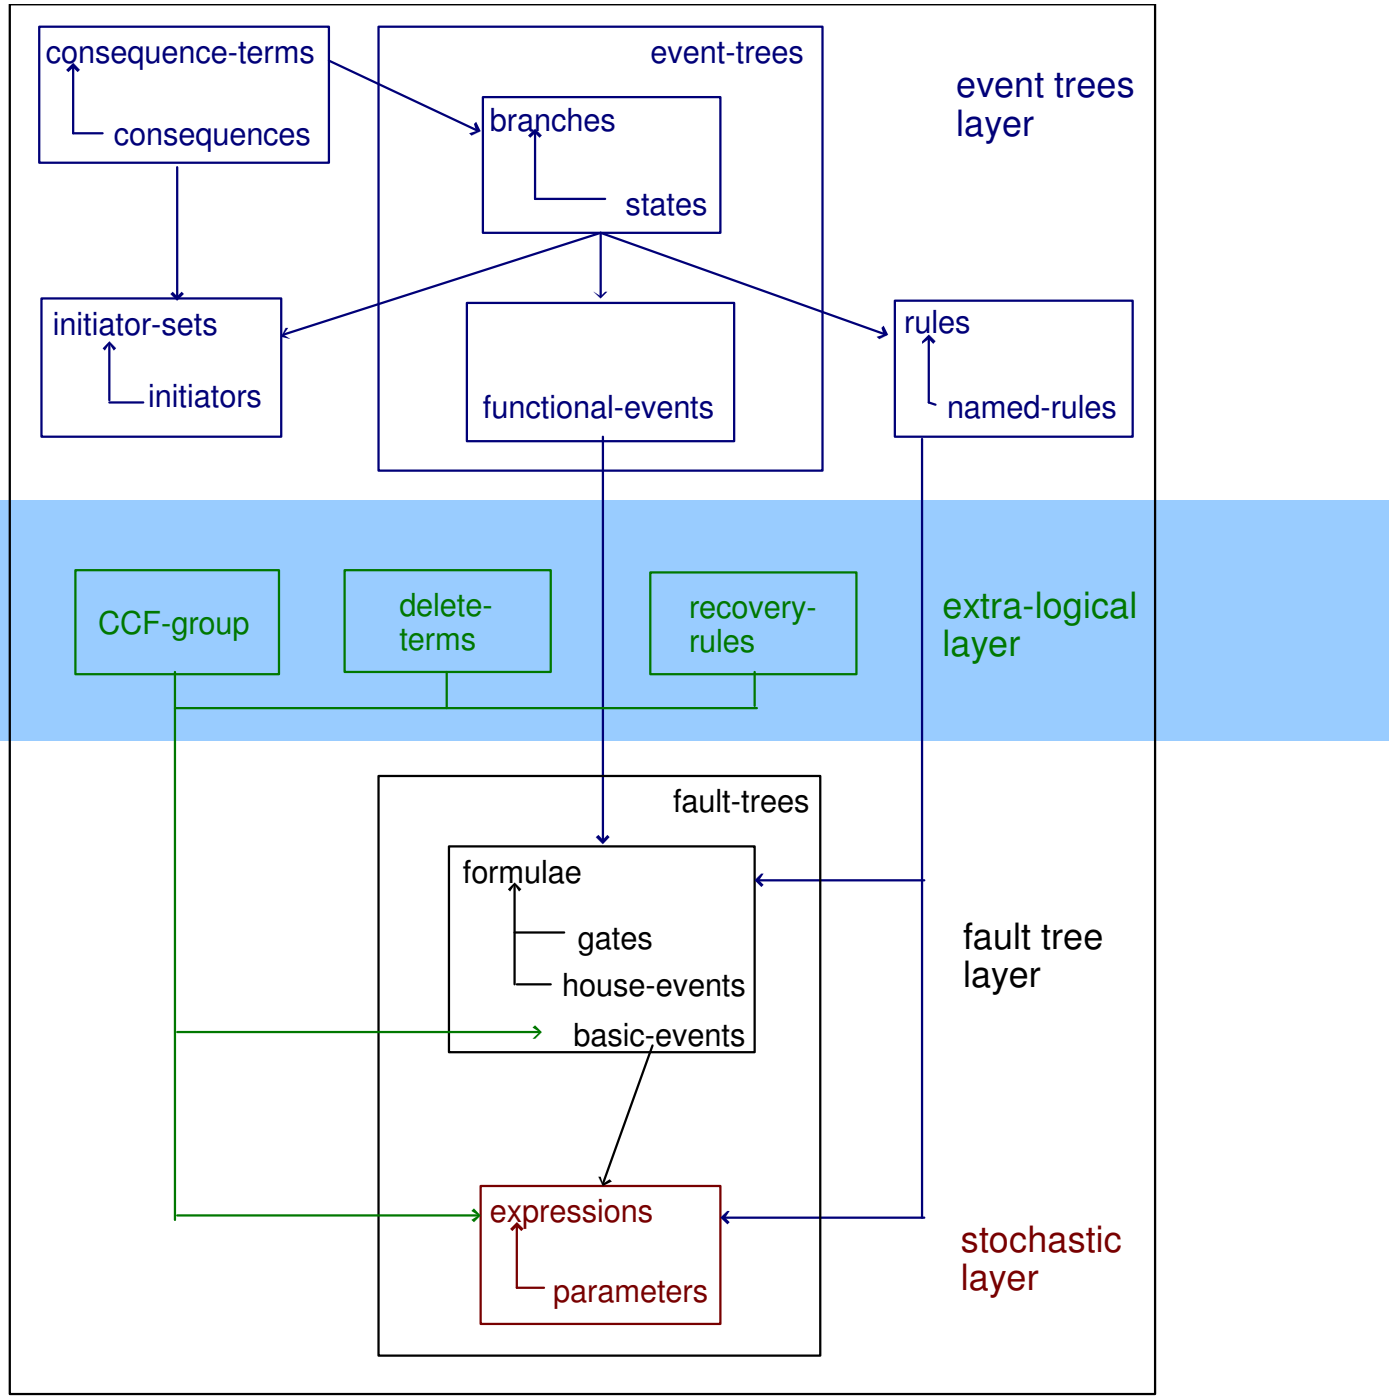


```
<histogram lower-bound="100" >
    <bin upper-bound="120" >
        <float value="1.0e-3 />
    </bin>
    <bin upper-bound="150" >
        <float value="2.0e-3 />
    </bin>
    <bin upper-bound="160">
        <float value="3.0e-3 />
    </bin>
</histogram>
```



The Open-PSA Initiative
Extra-Logical Layer

The Open-PSA Initiative



Extra-Logical Layer (Content)

1. Common Cause Failures
   - models, declarations
2. Exclusive events (delete terms)
   - model, declaration
3. Recovery rules
   - model, declaration

Delete Terms

Delete terms are groups of exclusive (basic) events.

- Used to model physically impossible configurations such as simultaneous maintenance

Three possible interpretations/uses of the exclusive group g={e1,e2}

1. Post-processing of cutsets
   - (e1 and e2 and ...) deleted
2. Global constraint
   - NewTopEvent = TopEvent and [not (e1 and e2)]
3. Local subsitution
   - e1 → ge1 = (e1 and not e2)
   - e2 → ge2 = (e2 and not e1)

Delete Terms (continued)

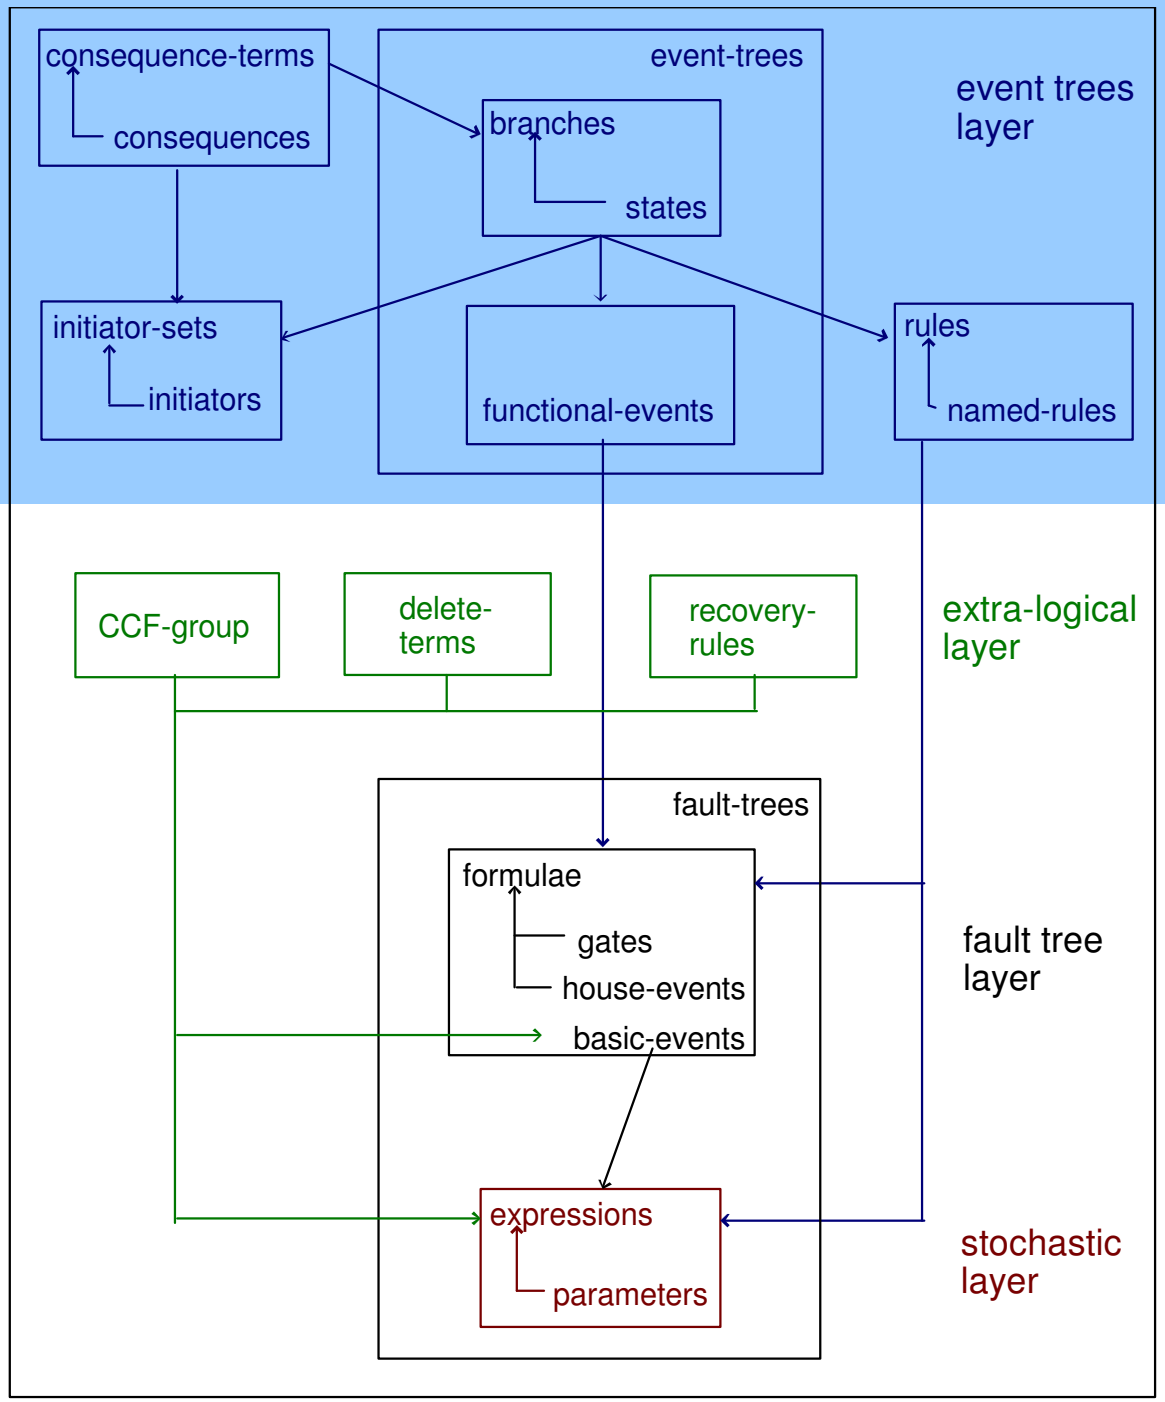
XML representation

```
<define-exclusive-group name="g1" >
    <basic-event name="e1" />
    <basic-event name="e2" />
    <basic-event name="e3" />
</define-exclusive-group>
```

The Open-PSA Initiative

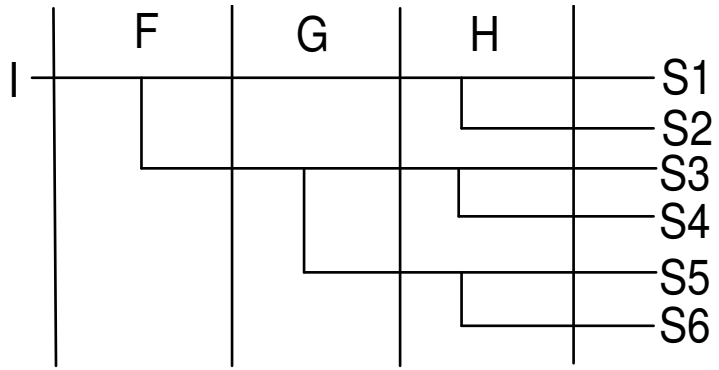
Event Tree Layer

The Open-PSA Initiative



Preliminaries (1)

Graphical presentation of Event Trees



Interpretation

S1 = I and not F and not H
S2 = I and not F and H
S3 = I and F and not G and not H
S4 = I and F and not G and H
S5 = I and F and G and not F
S6 = I and F and G and H

A priori simple but …

Preliminaries (2)

- Fault trees may be given flavors (by setting house events)
- These flavors may depend on the current branch
- There may have several initiating events
- Some success branches may be interpreted as a bypass
- There may have multi-states branches
- Branches may be defined as references to other branches
- …

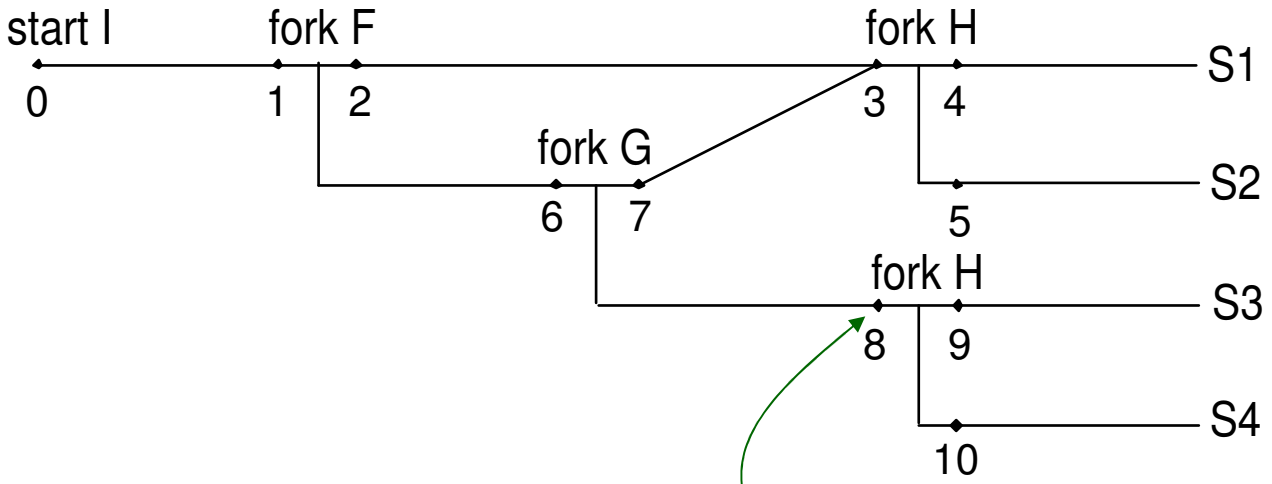
Preliminaries (2)

- Fault trees may be given flavors (by setting house events)
- These flavors may depend on the current branch
- There may have several initiating events
- Some success branches may be interpreted as a bypass
- There may have multi-states branches
- Branches may be defined as references to other branches
- …

Event Trees should be seen as a graphical programming language!

  - The graphical view described the structure of the tree, i.e. the different sequences
  - Instructions are provided to give flavors to fault trees
  - The interpretation of sequences (Boolean formula) is built while walking along the branches

Structure of Event Trees (1)



Walk:

- 0, 1, 2, 3, 4 (S1)
- 0, 1, 2, 3, 5 (S2)
- 0, 1, 6, 7, 3, 4 (S1)
- …

at each point some instructions can be executed in order to set values of house events and parameters and/or to collect functional event

Structure of Event Trees (2)

```
<define-event-tree name="ET1" >
   <define-functional-event name="F">          declarations of functional events
      <fault-tree name="FTF" gate="top" />
   </define-functional-event>
   …
   <define-consequence name="S1" />            declarations of consequences
   …
   <path>                                      definition of the structure
      <fork functional-event="F" >
         <path>
            <collect functional-event="F" polarity="success" />
            <fork functional-event="H" >
               …
            </fork>                                        instruction
         </path>
         …
      </fork>
   </path>
</define-event-tree>
```

Instructions (1)

Instructions to set parameters/house event values

- <set house-event="H1" >
  <constant value="false" />
  </set-parameter>
- <set parameter="lambda" />
  <float value="0.001" />
  </set-parameter>

Instructions to collect functional events

- <collect functional-event="F" polarity="failure" />

Conditional instructions

- <if>
  <collected functional-event="F" />
  <set house-event="H2"> <constant value="true" /> </set>
  </fi>

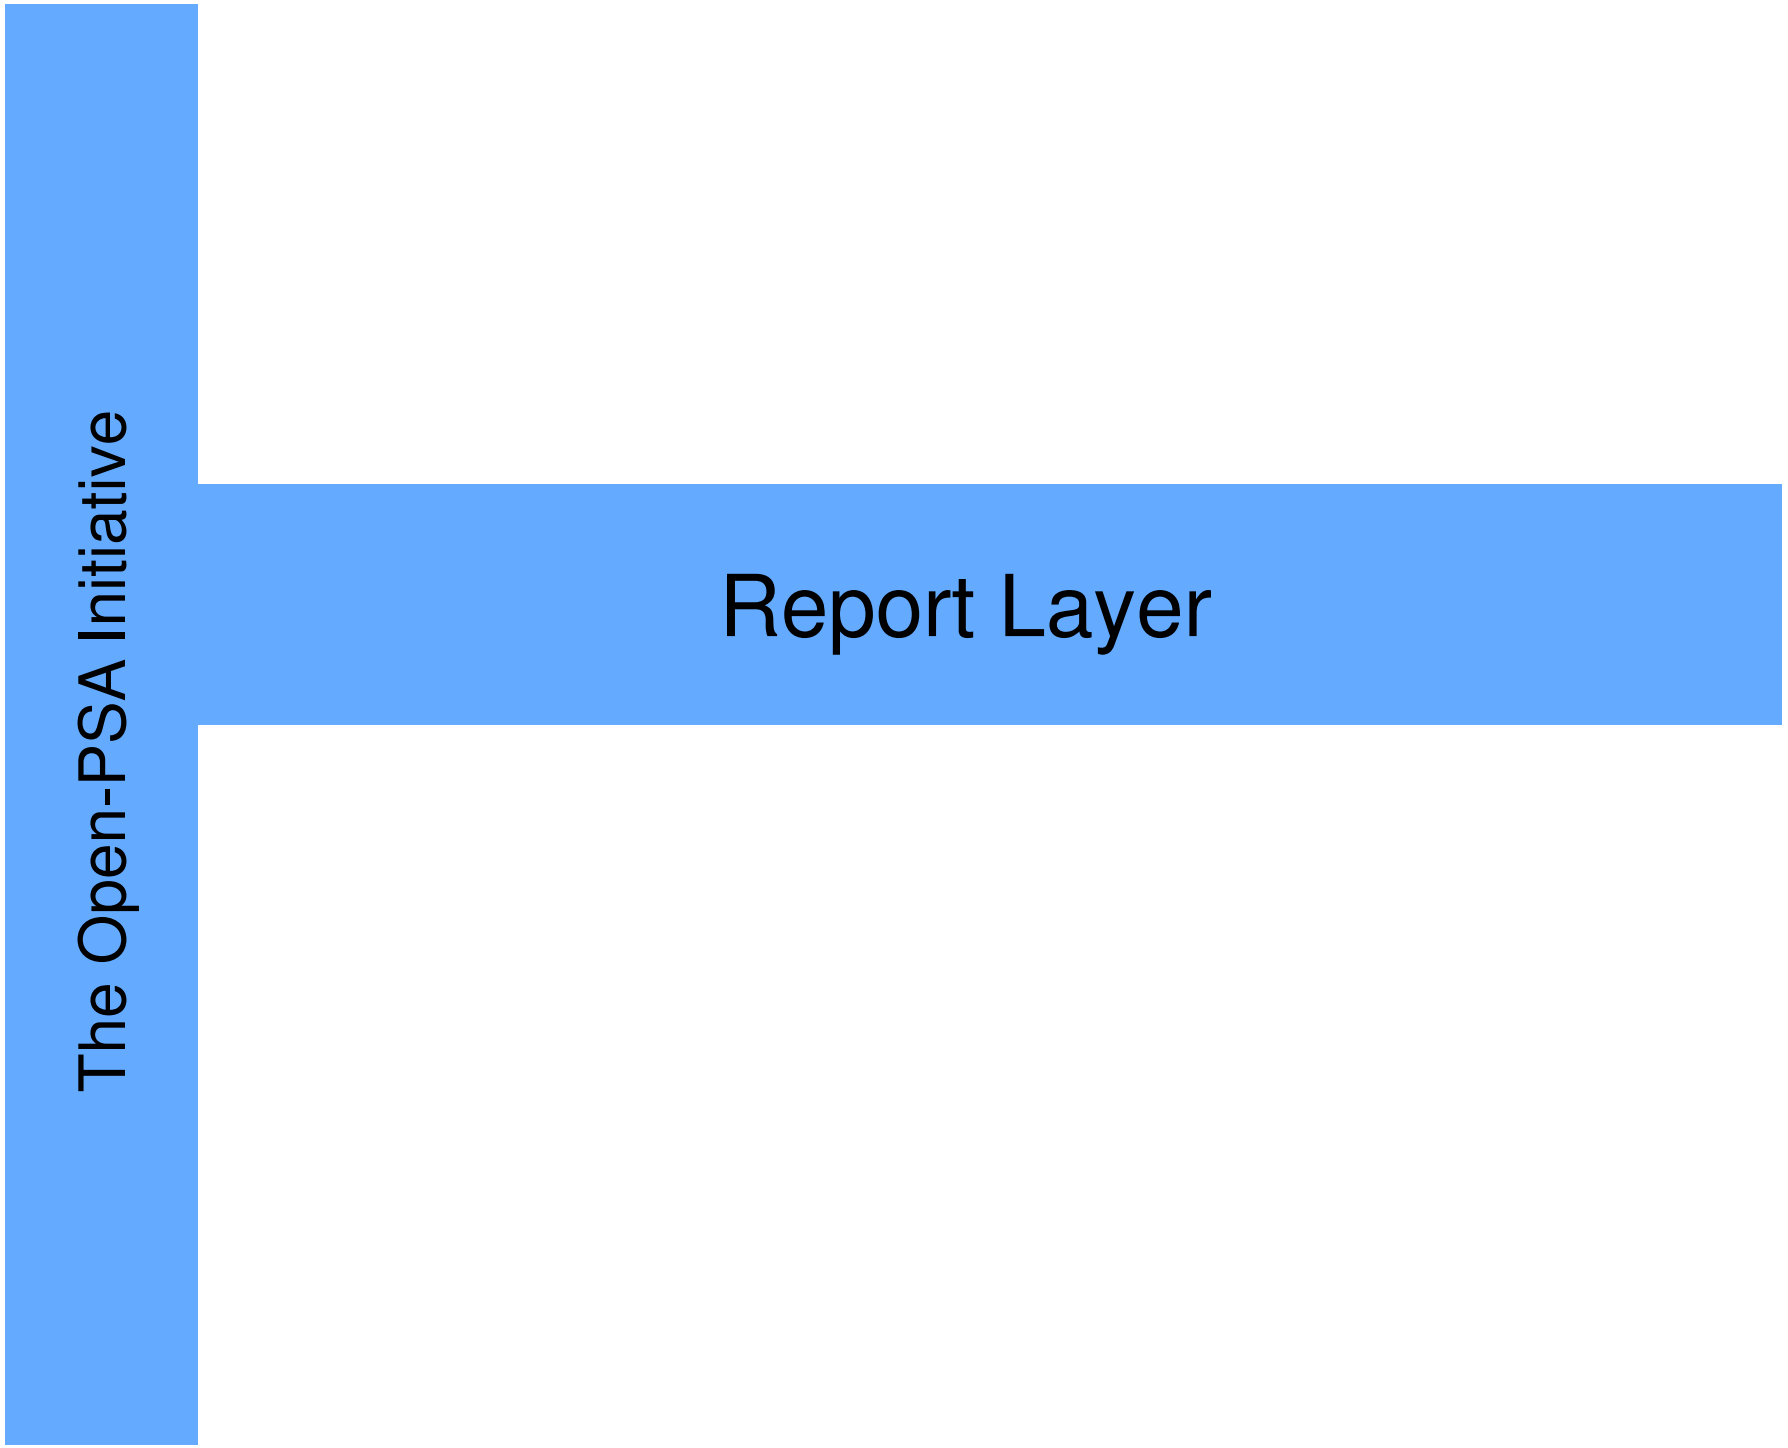
Instructions (2)

Blocks

- <block>
  instruction+
  </block>

Rules (named blocks of instructions)

- <define-rule name="R1" >
  <set house-event="H1"> <constant value="false" /> </set>
  <set house-event="H2"> <constant value="true" /> </set>
  <set house-event="H3"> <constant value="true" /> </set>
  …
  </define-rule>



The Open-PSA Initiative
Report Layer

Report Layer (content)

1. Description of Calculations
   - model, tool, algorithm, mission-time, cutoff...
2. Description of Results
   - minimal cutsets
   - probabilistic measures

Description of Calculations

- Software
  - version, contact organization (editor, vendor)
- Calculation algorithm
  - name
  - limits (number of basic events, cutsets...)
  - preprocessing techniques
  - cutoffs
  - handling of success branches, use of delete terms
  - external routines
  - calculation time
  - ...
- Feedback
  - success, failure

The standard provides examples rather than a strict syntax for these items

Descriptions of Results

```
<sum-of-products name="MCS1" basic-events="3" products="2" >
    <product order="2">
        <basic-event name="A" />
        <basic-event name="B" />
    </product>
    <product order="2">
        <not>
            <basic-event name="A" />
        </not>
        <basic-event name="C" />
    </product>
</sum-of-products>
```

Descriptions of Results

```
<measure name="RAW" system="TopEvent" component="BE33" >
    <mean value="0.00149807" />
    <standard-deviation value="0.000385405" />
    <error-factor percentage="90" value="1.00056" />
    <histogram lower-bound="0" >
        <bin upper-bound="0.25"> <float value="0.00112081"> </bin>
        <bin upper-bound="0.50"> <float value="0.00136203"> </bin>
        <bin upper-bound="0.75"> <float value="0.0016188">  </bin>
        <bin upper-bound="1.00"> <float value="0.00186128"> </bin>
    </histogram>
</measure>
```
